Javascript intl.numberformat parse, Javascript numberformat parse.

substring, substr Return the specified subset of the string, either by specifying the start and end indexes or the start index and a length. (Examples should be added to this page after MDN bug 857438 is fixed.) See also String.fromCodePoint() or String.prototype.codePointAt(). match, matchAll, replace, replaceAll, search Work with regular expressions. normalize Returns the Unicode Normalization Form of the calling string value. Unicode escape sequences The Unicode escape sequences require at least four hexadecimal digits following \u. This chapter introduces how to work with strings and text in JavaScript.JavaScript's String type is used to represent textual data. For example, the following code assigns helloLength the value 13, because "Hello, World!" has 13 characters, each represented by one UTF-16 code unit. Multi-lines Any new line characters inserted in the source are part of the template literal. startsWith, endsWith, includes Returns whether or not the string starts, ends or contains a specified string. Template literals can contain place holders. These are indicated by the Dollar sign and curly braces (\${expression}). Phonebook sort emphasizes sound, and it's as if "ä", "ö", and so on were expanded to "ae", "oe", and so on prior to sorting. For example, a string containing the single character U+1F600 "Emoji grinning face" will have length 2. A String object has a variety of methods; for example those that return a variation on the string itself, such as substring and toUpperCase. For example, there are actually two different sort orders in German, phonebook and dictionary. (The result is different in another time zone.) const msPerDay = 24 * 60 * 60 * 1000; const julY172014 = new Date(msPerDay * (44 * 365 + 11 + 197)); const options = { year: '2-digit', month: '2-digit', day: '2-digit', hour: '2-digit', minute: '2-digit', timeZoneName: 'short' }; const americanDateTime = new Intl.DateTimeFormat('en-US', options).format; console.log(americanDateTime(july172014)); The Intl.NumberFormat object is useful for formatting numbers, for example currencies. You can't change individual characters because strings are immutable array-like objects: const hello = 'Hello, World!'; const helloLength = hello.length; hello[0] = 'L'; hello[0]; Characters whose Unicode scalar values are greater than U+FFFF (such as some rare Chinese/Japanese/Korean/Vietnamese characters and some emoji) are stored in UTF-16 with two surrogate code units each. The following formats a date for English as used in the United States. indexOf, lastIndexOf Return the position of specified substring in the string or last position of specified substring, respectively. Accessing the individual code units in such a string using brackets may have undesirable consequences such as the formation of strings with unmatched surrogate code units, in violation of the Unicode standard. See also String.fromCodePoint() or String.prototype.codePointAt(). split Splits a String object into an array of strings by separating the string into substrings. concat Combines the text of two strings and returns a new string. Template literals are string literals allowing embedded expressions. The first element is at index 0, the next at index 1, and so on. This is a method of the String class, not a String instance. slice Extracts a section of a string and returns a new string. For example: const firstString = '2 + 2'; const secondString = new String(2 + 2); eval(firstString); eval(secondString); A String object has one property, length, that indicates the number of UTF-16 code units in the string. '\u{2F804}' '\uD87E\uDC04' The String object is a wrapper around the string primitive data type. toLowerCase, toUpperCase Return the string in all lowercase or all uppercase, respectively. repeat Returns a string consisting of the elements of the object. repeated the given times. The length of a String is the number of elements in it. You can access each code unit using an array bracket style. You can also use the String.length property with a string literal. Template literals are enclosed by the back-tick (` `) (grave accent) character instead of double or single quotes. The constructors for Intl.Collator, Intl.NumberFormat, and Intl.DateTimeFormat objects are properties of the Intl object.The Intl.DateTimeFormat object is useful for formatting date and time. Method Description charAt, charCodeAt, codePointAt Return the character or character code at the specified position in string. const germanDictionary = new Intl.Collator('de-DE-u-co-dict'); console.log(names.sort(germanDictionary.compare).join(' ')); For more information about the Intl API, see also Introducing the JavaScript Internationalization API. trim Trims whitespace from the beginning and end of the string. You can use multi-line strings and string interpolation features with them. Each element in the String occupies a position in the String. It is a set of "elements" of 16-bit unsigned integer values (UTF-16 code units). You should use string literals unless you specifically need to use a String object, because String objects can have counterintuitive behavior. You can create strings using string literals or string objects.You can create simple strings using either single or double quotes. More advanced strings can be created using escape sequences: Hexadecimal escape sequences The number after \x is interpreted as a hexadecimal number. const gasPrice = new Intl.NumberFormat('en-US', { style: 'currency', currency: 'USD', minimumFractionDigits: 3 }); console.log(gasPrice.format(5.259)); const banDecimalRMBInChina = new Intl.NumberFormat('zh-CN-u-nu-hanidec', { style: 'currency', currency: 'CNY' }); console.log(banDecimalRMBInChina.format(1314.25)); The Intl.Collator object is useful for comparing and sorting strings. const names = ['Hochberg', 'Högnigswald', 'Holzman']; const germanPhonebook = new Intl.Collator('de-DE-u-co-phonebk'); console.log(names.sort(germanPhonebook.compare).join(' ')); Some German words conjugate with extra umlauts, so in dictionaries it's sensible to order ignoring umlauts (except when ordering words differing only by umlauts: schon before schön). fromCharCode, fromCodePoint Constructs a string from the specified sequence of Unicode values. The following table summarizes the methods of String objects. With simple Unicode escapes it is often necessary to write the surrogate halves separately to achieve the same result. Using normal strings, you would have to use the following syntax in order to get multi-line strings: console.log('string text line 1\string text line 2'); To get the same effect with multi-line strings, you can now write: console.log(`string text line 1 string text line 2`); Embedded expressions In order to embed expressions within normal strings, you would use the following syntax: const five = 5; const ten = 10; console.log('Fifteen is ' + (five + ten) + ' and not ' + (2 * five + ten) + '.'); Now, with template literals, you are able to make use of the syntactic sugar making substitutions like this more readable: const five = 5; const ten = 10; console.log(`\${five + ten} and not \${2 \* five + ten}`.); For more information, read about Template literals in the JavaScript reference.The Intl object is the namespace for the ECMAScript Internationalization API, which provides language sensitive string comparison, number formatting, and date and time formatting. Unicode code point escapes New in ECMAScript 2015. const foo = new String('foo'); console.log(foo); typeof foo; You can call any of the methods of the String object on a string literal value—JavaScript automatically converts the string literal to a temporary String object, calls the method, then discards the temporary String object. With Unicode code point escapes, any character can be escaped using hexadecimal numbers so that it is possible to use Unicode code points up to 0x10FFFF.
